Solid solutions of the USb$_2$-ThSb$_2$ system have been synthesized for the first time and their magnetic properties are investigated at various temperatures (80–700°K). It is found that solutions containing less than 0.5 ThSb$_2$ are antiferromagnetic; the Neel temperature decreases with increasing ThSb$_2$ content. The effective number of Bohr magnetons $\mu_{\text{eff}}$, the paramagnetic Curie temperature $\theta_p$, and the lattice parameters have been determined for all compositions. A suggestion regarding the ground energy state of the U ion is made.

The magnetic properties of many antiferromagnetic uranium compounds of the type UX$_2$, where X = P, As, Sb, and Bi, have been recently investigated in the magnetically concentrated state. However, to obtain the most complete information concerning the character of the exchange interaction, it is of interest to investigate these compounds by replacing the uranium ions in them with thorium ions. Such a replacement is equivalent to magnetic dilution, since thorium has no 5f electrons and is a weakly-magnetic metal. We chose for the investigation the compound USb$_2$, which in accordance with is antiferromagnetic with a Neel temperature equal to 260°K; we also investigated USb$_2$-ThSb$_2$ solid solutions.

It was necessary to investigate, first, the very formation of the USb$_2$-ThSb$_2$ solid solutions, using an x-ray method, and, second, to obtain information on the ground state of the uranium ions in the solid solutions from the temperature dependence of the magnetic susceptibility and to establish the dependence of the critical temperature $T_N$ on the concentration of the weakly magnetic Th ion.

The compounds USb$_2$ and ThSb$_2$ have a structure of the Cu$_2$Sb type ($T_{\text{d}}^2=C$3b), and a space group $D_{\text{h}}^1 = P\overline{2}m m, m m, Z = 2$. The atoms U and Th occupy in the lattice the double position occupied in Cu$_2$Sb by the antimony, and for this reason the compounds USb$_2$ and ThSb$_2$ are anti-isomorphic to Cu$_2$Sb.

Since the metal atoms form a closest cubic packing following slight displacement, and the atoms Sb I are located in tetrahedral voids every other layer while the Sb II atoms occupy all the octahedral voids, the magnetic structure of the antiferromagnetic compound USb$_2$ is such that the magnetic moments of U have antiparallel directions in the basal planes and in the faces, and have a common direction along the C axis.

When the Th is diluted, the collinear magnetic structure of USb$_2$ should disintegrate. A preliminary synthesis of samples of dilute solutions of the system U$_{1-x}$Th$_x$Sb$_2$ was carried out by a previously described procedure. The samples obtained by this procedure were subsequently pressed and annealed in a vacuum of $10^{-6}$ mm Hg at a temperature of 1000°C for 100 hours.

Since the samples were highly pyrophoric, the entire operation on them was performed in an atmosphere of argon. The purities of the initial materials were U–99.9%, Th–99.9%, and Sb–99.9%. Powders of the prepared samples were subjected to an x-ray structure analysis (Cu K$_\alpha$ irradiation with Ni filter), which showed the presence of solid solutions in the entire concentration range from USb$_2$ to ThSb$_2$. The lattice parameters of the USb$_2$-ThSb$_2$ solid solution, depending on the composition of the alloy, varied linearly from $a = 4.27$ Å, $c = 8.74$ Å (USb$_2$) to $a = 4.34$ Å, $c = 9.15$ Å (ThSb$_2$), i.e., they satisfied the Vegard additivity law (Fig. 1).

The magnetic susceptibility was measured with a pendulum balance in the temperature interval from 80 to 650°K in magnetic fields from 1.5 to 10 kOe. It was established that the susceptibility $\chi$ of all the obtained samples does not depend on the applied external magnetic field, and in the case of the ThSb$_2$ compound it is also independent of the temperature and equals $-90 \times 10^{-6}$. The USb$_2$ compound and the solid solutions U$_{0.07}$Th$_{0.03}$Sb$_2$, U$_{0.07}$Th$_{0.03}$Sb$_2$, and U$_{0.7}$Th$_{0.3}$Sb$_2$ are antiferromagnetic. The temperature dependence of the susceptibility has maxima that shift towards lower temperatures with increasing dilution and become gradually smeared out, so that the maximum of the U$_{0.7}$Th$_{0.3}$Sb$_2$ sample is very weakly pronounced (Fig. 2).

Samples with large thorium contents are paramagnetic in the entire investigated temperature range. From the obtained experimental data on the specific susceptibility we calculated the susceptibility per uranium ion in the solid solution. At the same time, a correction was introduced for the diamagnetic susceptibility of the ThSb$_2$ solvent, and also for the diamagnetism of USb$_2$. 

FIG. 1. Variation of the lattice parameters of USb$_2$-ThSb$_2$ solid solutions.
Fig. 2. Specific susceptibility $\chi$ vs. temperature in the $\text{USb}_2\text{ThSb}_2$ system. The arrows denote the Néel temperatures: Curves: 1 - $\text{USb}_2\text{Th}_0\text{Sb}_2$; 2 - $\text{USb}_0\text{Th}_0\text{Sb}_2$; 3 - $\text{USb}_0\text{Th}_0\text{Sb}_2$; 4 - $\text{USb}_0\text{Th}_0\text{Sb}_2$. The variation of the Néel temperature $T_N$ with the composition is shown in the insert.

Fig. 3. Reciprocal susceptibility $1/\chi$ vs. the temperature in the $\text{USb}_2\text{ThSb}_2$ system. 1 - $\text{USb}_2$ [1], 2 - $\text{USb}_0\text{Th}_0\text{Sb}_2$, 3 - $\text{USb}_0\text{Th}_0\text{Sb}_2$, 4 - $\text{USb}_0\text{Th}_0\text{Sb}_2$, 5 - $\text{USb}_0\text{Th}_0\text{Sb}_2$, 6 - $\text{USb}_0\text{Th}_0\text{Sb}_2$, 7 - $\text{USb}_0\text{Th}_0\text{Sb}_2$, 8 - $\text{USb}_0\text{Th}_0\text{Sb}_2$.

The temperature dependence of the reciprocal specific susceptibility $1/\chi$, with allowance for the corrections for the diamagnetism, is shown in Fig. 3. We see that in the temperature region from 200 to 600°K, the compounds $\text{USb}_2$ and the solutions $\text{USb}_0\text{Th}_0\text{Sb}_2$, $\text{USb}_0\text{Th}_0\text{Sb}_2$, and $\text{USb}_0\text{Th}_0\text{Sb}_2$ satisfy the Curie-Weiss law. This has made it possible to determine the paramagnetic Curie temperature $\Theta_P$ and to calculate the effective number of Bohr magnetons per $U$ ion in the solid solution. For the composition $\text{USb}_0\text{Th}_0\text{Sb}_2$, the Curie-Weiss law is satisfied in a narrower temperature interval, from 350 to 650°K. In the temperature region 80-350°K, a noticeable deviation from this law is observed. The deviation is particularly pronounced in $\text{USb}_0\text{Th}_0\text{Sb}_2$ and $\text{USb}_0\text{Th}_0\text{Sb}_2$ in the temperature region from 420 to 650°K. By plotting the dependence of $1/\chi$ on $1/(T - \Theta_P)$ and extrapolating it to the temperature axis, we determined the temperature-independent susceptibility, which for these compounds turned out to be $+0.3 \times 10^{-6}$ cm$^3$ g$^{-1}$. Curve 8 of Fig. 3 has been plotted with allowance for the temperature-independent part of the susceptibility. We see that in the temperature region 80-150°K the reciprocal susceptibility does not follow a linear law. At higher temperatures, however, the Curie-Weiss law is satisfied. The values of $\Theta_P$ and $\mu_{\text{eff}}$ for all the investigated compositions are listed in the table and are shown in Fig. 4.

It follows from the experimental data that as the uranium ions become replaced by the thorium ions, the antiferromagnetic transformation shifts nonlinearly towards lower temperatures, depending on the concentration (Fig. 2). Such a shift was predicted by Blume[6] for a system with magnetic ions in a state with a ground singlet level $\Gamma_1$ and located somewhat higher than the triplet levels $\Gamma_3$. For other antiferromagnetic systems, namely $\text{MnO-MgO}$ and $\text{CaO-MgO}$, a linear shift of $\Theta_N$ as a function of the concentration is observed, which is typical of ions with a magnetic ground energy level[7].

**Does not depend on the temperature.
MAGNETIC PROPERTIES OF USb₂–ThSb₂ SOLID SOLUTIONS

As established for many compounds[8], in the case of a nonmagnetic ground level in the absence of exchange interactions, the susceptibility may be independent of the temperature in a certain temperature interval (the Van Vleck paramagnetism). The observed deviations from the Curie-Weiss law in the temperature region 80–150°K are possibly due to the appearance of a temperature-independent susceptibility. However, it is not excluded that these deviations are connected with the formation of “clusters” in the USb₂-ThSb₂ solid solutions. The affected number of Bohr magnetons per uranium ion in the solid solution increases with increasing substitution, and approaches the value calculated for the “quenched” orbital momentum for the ground state \(^3\text{H}_4\) (2.83 \(\mu_B\)).

As to the deviation from the Curie-Weiss law in the high-temperature region, this is apparently connected with the paramagnetism of the conduction electrons. It should be noted that a final solution to the problem of the ground energy state of the uranium ion in these compounds calls for further magnetic measurements at lower temperatures.

Additional information on the magnetic properties of solid solutions can be obtained from temperature investigations of the Mössbauer spectra, which are presently under way.
